

a Sparse finite-peer fields

dot = one peer, stacked inwards where a 24-bin cell holds several; grey triangle = focal reference at relative phase 0. Realization r00 shown; the antipodal fields are $\kappa = 6$ partner-paired draws.

b Trinomial response by sparse field

left / right bar = seed block 1 / 2 (independent estimates); each bar averages 6 realizations

c Peer-count dependence

open = this campaign (tinted) · filled = stimulus-domain campaign; spliced sources, not a controlled sweep. Antipodal $\kappa = 6$ only; no peer-8 antipodal field exists, so $N = 8$ is not shown.

d Variance decomposition

e Exact balance (8:8): abstention

f One-peer majority activation

■ encoding effect ● physical realization ▲ seed block (LLM re-sampling)

◆ mean $\pm$ 95% CI over 6 realizations ● small = one realization □ open = integer-count $N = 16$ antipodal field (other acquisition)

Exact balance is stable, not a one-draw fluke: moments $A = 0.021$ – 0.062 across realizations (SD 0.015), against $A = 0.992$ at 9:7. Realizations are independent draws at each imbalance, so lines in f join means, not matched fields.
